Motorddiag Komfort Manager Full 2.0 Cracinstmank -..A virtual machine is a software implementation of a physical computer that can execute programs, which in this example, is made up of one or more guest systems. The guest systems utilize a virtual machine monitor (VMM), which supports the virtualization of the physical hardware by providing interfaces between the guest systems and the physical resources. Examples of physical resources provided by the VMM include central processing units (CPUs), memory, input/output (I/O) devices, and other types of devices that can be shared between one or more guest systems. A virtual machine monitor, as well as virtual machine environments such as a virtual machine hypervisor, a server hypervisor, a server virtual machine monitor, or a cluster management operating system may provide device mappings, which map a set of I/O devices that may be shared by the virtual machines to a set of physical I/O devices (e.g., input/output (I/O) device adapter(s), physical bus, and physical I/O port(s)). Such device mappings can include virtualization of I/O address space and I/O data space. The mapping between the virtual device(s) and the physical device(s) can be performed in hardware or in software. In the hardware approach, an address translation module can be used to perform the mapping. The address translation module receives a virtual memory address, which can be either virtual address space or physical address space. The module then translates the virtual memory address to physical memory address using a translation table. In the software approach, an address mapping module can be used to perform the mapping. In current approaches, the VMM may perform an additional role of enforcing a degree of privilege isolation between guest systems. For example, for protection of non-uniform memory access (NUMA) computer systems, a virtual machine monitor may have a set of privileges in such a way that the virtual machines running on a node will only have read-only access to the resources available on the node. On the other hand, the virtual machine monitor may have write privileges on all other nodes. This can help in limiting a potential attack vector.
